Taylor series and Taylor's theorem

Taylor series:

Assuming function f(x) has derivatives of any order, the Taylor series expansion of x about the point x_0 is

$$f(x) = \sum_{n=0}^{\infty} \frac{f^{(n)}(x_0)}{n!} (x - x_0)^n,$$

where $f^{(n)}(x_0)$ is the *n*th-order derivative at x_0 .

Taylor's theorem:

Let $N \ge 1$ be an integer and let the function f(x) be N times differentiable at the point x_0 , then

$$f(x) = f(x_0) + \sum_{n=1}^{N} \frac{f^{(n)}(x_0)}{n!} (x - x_0)^n + o\left(|x - x_0|^N\right),$$

The notation for the remainder, $o(|x - x_0|^N)$, means that the remainder is small compared to $|x - x_0|^N$. Formally, $\lim_{x \to x_0} \frac{o(|x - x_0|^N)}{|x - x_0|^N} = 0$.

Stabilization

Local approximation

The vector form of the approximations:

linear:

$$f(\mathbf{x}) \approx f(\mathbf{x}_0) + \mathbf{g}_{\mathbf{x}_0}^T(\mathbf{x} - \mathbf{x}_0);$$

and quadratic:

$$f(\mathbf{x}) \approx f(\mathbf{x}_0) + \mathbf{g}_{\mathbf{x}_0}^T(\mathbf{x} - \mathbf{x}_0) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_0)^T \mathbf{H}_{\mathbf{x}_0}(\mathbf{x} - \mathbf{x}_0).$$

Here $\mathbf{g}_{\mathbf{x}_0}$ and $\mathbf{H}_{\mathbf{x}_0}$ are the *gradient* and *Hessian matrix* of $f(\mathbf{x})$ at \mathbf{x}_0 . **H** is *square* and *symmetric*. We also call $\partial f = f(\mathbf{x}) - f(\mathbf{x}_0)$ and $\partial \mathbf{x} = \mathbf{x} - \mathbf{x}_0$ the *function perturbation* and *perturbation vector* (at \mathbf{x}_0).

Exercise 1: Find the second-order "approximation" for $f(\mathbf{x}) = (3 - x_1)^2 + (4 - x_2)^2$. How many local minima do we have? What is special about the Hessian?

Exercise 2: Find the quadratic approximation of the function:

$$f(\mathbf{x}) = 2x_1 + x_1^{-2} + 2x_2 + x_2^{-2}, \quad \mathbf{x} \in \mathbb{R}^2, \mathbf{x} \neq (0, 0)^T.$$

Is the Hessian positive definite? Is the problem bounded?

The function has positive definite Hessian everywhere in its feasible domain, but its function value is unbounded.

	00000000000	000000	000	000

Necessary and sufficient conditions

first-order necessary condition

If $f(\mathbf{x})$, $x \in \mathcal{X} \subseteq \mathbb{R}^n$, has a local minimum at an interior point \mathbf{x}_* of the set \mathcal{X} and if $f(\mathbf{x})$ is continuously differentiable at \mathbf{x}_* , then $\mathbf{g}_{\mathbf{x}_*} = \mathbf{0}$.

second-order optimality condition

Let $f(\mathbf{x})$ be twice differentiable at the point \mathbf{x}_* .

- 1. (necessity) If \mathbf{x}_* is a local solution, then $\mathbf{g}_{\mathbf{x}_*} = \mathbf{0}$ and Hessian is positive-semidefinite.
- 2. (sufficiency) If the Hessian of f(x) is positive-definite at a stationary point \mathbf{x}_* , i.e., $\mathbf{g}_{\mathbf{x}_*} = \mathbf{0}$, then \mathbf{x}_* is a local minimum.

< □ > < @ > < E > < E > E < 388

Exercise 3: Find the solution(s) for $\min_{\mathbf{x}\in\mathbb{R}^2}$ $f(\mathbf{x}) = 4x_1^2 - 4x_1x_2 + x_2^2 - 4x_1 + 2x_2$.

What about first-order sufficient condition?

Outline	preliminaries	gradient descent	Newton's method	Exercise	Stabi
	00000000000	0000000	000	000	000

Proof for first-order necessary condition

From first-order approximation at \mathbf{x}_* we have:

$$f(\mathbf{x}) = f(\mathbf{x}_{*}) + \mathbf{g}_{\mathbf{x}_{*}}^{T}(\mathbf{x} - \mathbf{x}_{*}) + o(||\mathbf{x} - \mathbf{x}_{*}||).$$
(1)

< ロ ト < @ ト < 注 ト < 注 ト 注 ?????

Let $\mathbf{x} = \mathbf{x}_* - t\mathbf{g}_{\mathbf{x}_*}$. (Here we deliberately pick $-\mathbf{g}_{\mathbf{x}_*}$ as the direction.) Since \mathbf{x}_* is a local solution, we have $f(\mathbf{x}_* - t\mathbf{g}_{\mathbf{x}_*}) - f(\mathbf{x}_*) \ge 0$, $\forall t > 0$. Take Equation (1) into account to have:

$$0 \leq \frac{f(\mathbf{x}_* - t\mathbf{g}_{\mathbf{x}_*}) - f(\mathbf{x}_*)}{t} = -||\mathbf{g}_{\mathbf{x}_*}||^2 + \frac{o(t||\mathbf{g}_{\mathbf{x}_*}||)}{t}.$$

Taking $t \to 0$, we have $0 \le -||\mathbf{g}_{\mathbf{x}_*}||^2 \le 0$, requiring $\mathbf{g}_{\mathbf{x}_*} = 0$.

Outline	preliminaries	gradient descent	Newton's method	Exercise	Stabilization
	00000000000	0000000	000	000	000

Proof for second-order necessary condition

From second-order approximation at \mathbf{x}_* we have:

$$f(\mathbf{x}) = f(\mathbf{x}_*) + \mathbf{g}_{\mathbf{x}_*}^T(\mathbf{x} - \mathbf{x}_*) + \frac{1}{2}(\mathbf{x} - \mathbf{x}_*)^T \mathbf{H}_{\mathbf{x}_*}(\mathbf{x} - \mathbf{x}_*) + o(||\mathbf{x} - \mathbf{x}_*||^2).$$
(2)

Let $\mathbf{x} = \mathbf{x}_* + t\mathbf{d}$, where \mathbf{d} is a unit direction, i.e., $||\mathbf{d}|| = 1$. Using first-order necessary condition, and the fact that \mathbf{x}_* is a local solution, we have

$$0 \leq \frac{f(\mathbf{x}_* + t\mathbf{d}) - f(\mathbf{x}_*)}{t} = \frac{1}{2}\mathbf{d}^T \mathbf{H}_{\mathbf{x}_*}\mathbf{d} + \frac{o(t^2)}{t^2}.$$

Taking $t \to 0$, we have $0 \le \mathbf{d}^T \mathbf{H}_{\mathbf{x}_*} \mathbf{d}$. Since *d* is arbitrarily chosen, we have that $\mathbf{H}_{\mathbf{x}_*}$ is positive semi-definite.

The Hessian at the stationary point is positive semidefinite, but the stationary point is not a local minimum.

utline	preliminaries
	00000000

Stabilization

Convex sets and convex functions

Definition (convex set)

A set $S \in \mathbb{R}^n$ is convex if, for every point $\mathbf{x}_1, \mathbf{x}_2$ in S, the point

$$\mathbf{x}(\lambda) = \lambda \mathbf{x}_2 + (1 - \lambda)\mathbf{x}_1, \quad 0 \le \lambda \le 1$$

belongs also to the set.

Definition (convex function)

A function $f : \mathcal{X} \to \mathbb{R}$, $\mathcal{X} \in \mathbb{R}^n$ defined on a nonempty convex set \mathcal{X} is called convex on \mathcal{X} if and only if, for every $\mathbf{x}_1, \mathbf{x}_2 \in \mathcal{X}$:

$$f(\lambda \mathbf{x}_2 + (1-\lambda)\mathbf{x}_1) \le \lambda f(\mathbf{x}_2) + (1-\lambda)f(\mathbf{x}_1),$$

where $0 \le \lambda \le 1$.

Exercise 4: Show the intersection of convex sets is convex; Show $f_1 + f_2$ is convex on the set S if f_1, f_2 are convex on S.

Exercise 5: Show that $f(\mathbf{x}_1) \ge f(\mathbf{x}_0) + \mathbf{g}_{\mathbf{x}_0}^T(\mathbf{x}_1 - \mathbf{x}_0)$ for a convex function.

Outline	preliminaries	gradient descent	Newton's method	Exercise	Stabilization
	00000000 00	0000000	000	000	000

Convex sets and convex functions

A differentiable function is convex if and only if its Hessian is positive-semidefinite in its entire convex domain. (hint: use Taylor's theorem to have $f(\mathbf{x}_1) = f(\mathbf{x}_0) + \mathbf{g}_{\mathbf{x}_0}^T(\mathbf{x}_1 - \mathbf{x}_0) + 1/2(\mathbf{x}_1 - \mathbf{x}_0)^T H_{\mathbf{x}(\lambda)}(\mathbf{x}_1 - \mathbf{x}_0)$, for $\mathbf{x}(\lambda) = \lambda \mathbf{x}_1 + (1 - \lambda) \mathbf{x}_0$.)

A positive-definite Hessian implies *strict* convexity, but the converse is generally not true. Example?

first-order sufficient condition

If a differentiable convex function with a convex open domain has a stationary point, this point will be the global minimum. If the function is strictly convex, then the minimum will be unique.

If the function is convex but not strictly convex, will the minimum be unique?

If the function is strictly convex, will the minimum be not unique?

Outline	preliminaries	gradient descent	Newton's method	Exercise	Stabilization
	00000000000	00 0000	000	000	000
Gradier	nt descent				

In reality it is hard to solve for the optimal solution \mathbf{x}_* by hand because (i) the system of equations from the first-order necessary condition may not be easy to solve or (ii) the objective may not have an analytical form. Therefore, we need an *iterative* procedure to produce a series $\mathbf{x}_0, \mathbf{x}_1, ..., \mathbf{x}_k$ that converges to \mathbf{x}_* .

One naive way is to use the following: $\mathbf{x}_{k+1} = \mathbf{x}_k - \mathbf{g}_k$. Why?

Exercise 6: Try this method for the following problem

$$\min_{\mathbf{x}} \quad f(\mathbf{x}) = x_1^4 - 2x_1^2 x_2 + x_2^2$$

with $\mathbf{x}_0 = (1.1, 1)^T$. Explain your observation.

Armijo line search

In Armijo line search, we construct a function

$$\phi(\alpha) = f_k + \alpha t \mathbf{g}_k^T \mathbf{s}_k,$$

for some $t \in [0.01, 0.3]$ and denote $f(\alpha) := f(\mathbf{x}_k + \alpha \mathbf{s}_k)$. Starting with a large value (default $\alpha = 1$), α is reduced by $\alpha = b\alpha$ for some $b \in [0.1, 0.8]$ until $f(\alpha) < \phi(\alpha)$, at which point it is guaranteed that $f(\alpha) < f_k$, since $\phi(\alpha) < f_k$ by nature.

Newton's method

Instead of using second-order approximation in line search, we can use it to find the direction.

$$f_{k+1} = f_k + \mathbf{g}_k \partial \mathbf{x}_k + \frac{1}{2} \partial \mathbf{x}_k^T \mathbf{H}_k \partial \mathbf{x}_k.$$

The first-order necessary condition for minimizing the approximated f_{k+1} requires $\mathbf{x}_{k+1} = \mathbf{x}_k - \mathbf{H}_k^{-1}\mathbf{g}_k$. If the function is locally strictly convex, this iteration will yield a lower function value. Newton's method will move efficiently in the neighborhood of a local minimum where local convexity is present.

	00000000000	000000	000	000	•00
Stabi	lization				

Given a symmetric matrix \mathbf{M}_k , the gradient and Newton's methods can be classed together by the general iteration

$$\mathbf{x}_{k+1} = \mathbf{x}_k - \alpha \mathbf{M}_k \mathbf{g}_k,$$

where $\mathbf{M}_k = \mathbf{I}$ for gradient descent and $\mathbf{M}_k = \mathbf{H}_k^{-1}$ for Newton's method.

By the first-order Taylor approximation $f_{k+1} - f_k = -\alpha \mathbf{g}_k^T \mathbf{M}_k \mathbf{g}_k$, descent is accomplished for positive-definite \mathbf{M}_k .

To ensure descent, we can use $\mathbf{M}_k = (\mathbf{H}_k + \mu_k \mathbf{I})^{-1}$ and select a positive scalar μ_k .

Outline	preliminaries	gradient descent	Newton's method	Exercise	Stabilization
	00000000000	000000	000	000	000
Trust	region $(1/2)$				

Newton's method is faster if \mathbf{x}_k is close to \mathbf{x}_* . If the search length $||\alpha \mathbf{H}_k \mathbf{g}_k||$ is really short or if \mathbf{H}_k is very different from the Hessian at \mathbf{x}_* , then $-\mathbf{g}_k$ may be a better direction to search.

Trust region algorithm: search using a quadratic approximation, but restrict the search step within the trust region with radius Δ at \mathbf{x}_k :

$$\min_{\mathbf{s}} \qquad f \approx \mathbf{g}_k^T \mathbf{s} + \frac{1}{2} \mathbf{s}^T \mathbf{H}_k \mathbf{s}$$

subject to $||\mathbf{s}|| \le \Delta$

If $||\mathbf{s}|| \leq \Delta$ then

$$\mathbf{s}_k = -\mathbf{H}_k^{-1}\mathbf{g}_k \quad ||\mathbf{H}_k^{-1}\mathbf{g}_k|| < \Delta,$$

or if $||\mathbf{s}|| = \Delta$ then

$$\mathbf{s}_k = -(\mathbf{H}_k + \mu \mathbf{I})^{-1} \mathbf{g}_k, \mu > 0, \quad ||\mathbf{s}_k|| = \Delta.$$

Trust region (2/2)

Given Δ , we evaluate at $f(\mathbf{x}_k + \mathbf{s}_k)$ and calculate the ratio

$$r_k = \frac{f(\mathbf{x}_k) - f(\mathbf{x}_k + \mathbf{s}_k)}{-(\mathbf{g}_k^T \mathbf{s}_k + \frac{1}{2} \mathbf{s}_k^T \mathbf{H}_k \mathbf{s}_k)}$$

The trust region radius is increased when $r_k > 0.75$ (indicating a "good step") and decreased when $r_k < 0.25$ (indicating a "bad step").

Algorithm 3 Trust region algorithm

- 1: Start with \mathbf{x}_0 and $\Delta_0 > 0$. Set k = 0.
- 2: Calculate the step \mathbf{s}_k .
- 3: Calculate the value $f(\mathbf{x}_k + \mathbf{s}_k)$ and the ratio r_k .
- 4: If $f(\mathbf{x}_k + \mathbf{s}_k) \ge f(\mathbf{x}_k)$, then set $\Delta_{k+1} = \Delta_k/2$, $\mathbf{x}_{k+1} = \mathbf{x}_k$, k = k + 1 and go to Step 3.
- 5: Else, set $\mathbf{x}_{k+1} = \mathbf{x}_k + \mathbf{s}_k$. If $r_k < 0.25$, then set $\Delta_{k+1} = \Delta_k/2$; if $r_k > 0.75$, then set $\Delta_{k+1} = 2\Delta_k$; otherwise set $\Delta_{k+1} = \Delta_k$. Set k = k+1 and go to Step 2.
